

04 - Iteration Control Structures

For example:

Input	Result
20	1 2 4 5 10 20

Ex. No. : 4.1

Date:

Register No.:

Name:

Factors of a number

Determine the factors of a number (i.e., all positive integer values that evenly divide into a number).

```
def factors(n):
    factors =[]
    for i in range(1,int
(n**0.5) +1):
        if n%i==0:
            factors.append(i)
            if i!=n//i:
                factors.append(n//i)
    factors.sort()
    return factors

n=int(input())
factors=find_factors
(n)
print( ' '.join(map
(str,factors)))
```

For example:

Input	Result
292	1
1015	2
108	3
22	0

Ex. No. : **4.2**

Date:

Register No.:

Name:

Non Repeated Digit Count

Write a program to find the count of non-repeated digits in a given number N. The number will be passed to the program as an input of type int.

Assumption: The input number will be a positive integer number ≥ 1 and ≤ 25000 .

Some examples are as below.

If the given number is 292, the program should return 1 because there is only 1 non-repeated digit '9' in this number

If the given number is 1015, the program should return 2 because there are 2 non-repeated digits in this number, '0', and '5'.

If the given number is 108, the program should return 3 because there are 3 non-repeated digits in this number, '1', '0', and '8'.

If the given number is 22, the function should return 0 because there are NO non-repeated digits in this number.

```
n=int(input())
k=str(n)
g=len(str(n))
count=0
v=[]
if(n>=1 and
n<=25000):
    for i in range(0,g):
        if(k[i] not in v):
            count+=1
            v.append(k[i])
print(count)
```

Example1: if the given number N is 7, the method must return 2

Example2: if the given number N is 10, the method must return 1

For example:

Input	Result
7	2
10	1

Ex. No. : 4.3

Date:

Register No.:

Name:

Prime Checking

Write a program that finds whether the given number N is Prime or not. If the number is prime, the program should return 2 else it must return 1.

Assumption: $2 \leq N \leq 5000$, where N is the given number.

```
n=int(input())
count=0
if(n>=2 and
n<=5000):
    for i in range(2,n):
        if(n%i==0):
            print(1)
            count+=1
            break
    if(count==0):
        print(2)
```

Input Format:

Integer input from stdin.

Output Format:

Perfect square greater than N.

Example Input:

10

Output:

16

Ex. No. : 4.4

Date:

Register No.:

Name:

Next Perfect Square

Given a number N, find the next perfect square greater than N.

```
n=int(input())
for i in range(1,10):
    p=i*i
    if(p>n):
        break
    print(p)
```

NOTE: Fibonacci series looks like –

0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, . . . and so on.

i.e. Fibonacci series starts with 0 and 1, and continues generating the next number as the sum of the previous two numbers.

- first Fibonacci number is 0,
- second Fibonacci number is 1,
- third Fibonacci number is 1,
- fourth Fibonacci number is 2,
- fifth Fibonacci number is 3,
- sixth Fibonacci number is 5,
- seventh Fibonacci number is 8, and so on.

For example:

Input:

7

Output

8

Ex. No. : 4.5

Date:

Register No.:

Name:

Nth Fibonacci

Write a program to return the nth number in the fibonacci series. The value of N will be passed to the program as input.

```
n=int(input())
a=0
b=1
sum=0
for i in range(1,n-1):
    fib=a+b
    a=b
    b=fib
    sum=b
print(sum)
```

Input Format:

Single Integer Input from stdin.

Output Format:

Yes or No.

Example Input:

175

Output:

Yes

Explanation

$$1^1 + 7^2 + 5^3 = 175$$

Example Input:

123

Output:

No

For example:

InputResult

175 Yes

123 No

Ex. No. : 4.6

Date:

Register No.:

Name:

Disarium Number

A Number is said to be Disarium number when the sum of its digit raised to the power of their respective positions becomes equal to the number itself. Write a program to print number is Disarium or not.

```
n=int(input())
k=len(str(n))
sum=0
c=n
count=k
for i in range (0,k):
    temp=c%10
    sum+=temp**count
    count-=1
    c//=10
if(sum==n):
    print("Yes")
else:
    print("No")
```

Sample Test Cases

Test Case 1

Input

4

Output

1234

Explanation:

as input is 4, have to take 4 terms.

$1 + 11 + 111 + 1111$

Test Case 2

Input

6

Output

123456

For example:

Input	Result
3	123

Ex. No. : 4.7

Date:

Register No.:

Name:

Sum of Series

Write a program to find the sum of the series $1 + 11 + 111 + 1111 + \dots + n$ terms (n will be given as input from the user and sum will be the output)

```
def series_sum(n):
    total=0
    current_term=1
    for i in range
        (1,n+1):
            total+=current_term
            current_term=current
            _term *10+1
    return total

n=int(input())
result=series_sum(n)
print(result)
```

For example:

Input	Result
292	2
1015	3

Ex. No. : 4.8

Date:

Register No.:

Name:

Unique Digit Count

Write a program to find the count of unique digits in a given number N. The number will be passed to the program as an input of type int.

Assumption: The input number will be a positive integer number ≥ 1 and ≤ 25000 .

For e.g.

If the given number is 292, the program should return 2 because there are only 2 unique digits '2' and '9' in this number

If the given number is 1015, the program should return 3 because there are 3 unique digits in this number, '1', '0', and '5'.

```
a=int(input())
l=[]
c=str(a)
k=len(str(a))
count=0
n=0
for i in range(0,k):
    l.append(c[i])
for i in range(0,k):
    flag=0
    for j in range(0,k):
        if(l[i]==l[j]):
            flag+=1
    if(flag==1):
        count+=1
print(count)
```

Input Format:

Single Integer input.

Output Format:

Output displays Yes if condition satisfies else prints No.

Example Input:

14

Output:

Yes

Example Input:

13

Output:

No

Ex. No. : **4.9**

Date:

Register No.:

Name:

Product of single digit

Given a positive integer N, check whether it can be represented as a product of single digit numbers.

```
a=int(input())
flag=0
for i in range(1,10):
    for j in range(i,10):
        if(i*j==a):
            flag=1
if(flag==1):
    print('Yes')
else:
    print('No')
```

Input Format:

Single integer input.

Output Format:

Yes or No.

Example Input:

24

Output:

Yes

Example Input:

26

Output:

No

For example:

Input	Result
24	Yes

Ex. No. : **4.10**

Date:

Register No.:

Name:

Perfect Square After adding One

Given an integer N, check whether N the given number can be made a perfect square after adding 1 to it.

```
def a(n):
    n+=1
    sqrt_n=n**0.5
    if int(sqrt_n) ==
sqrt_n:
        return "Yes"
    else:
        return "No"
```

```
n=int(input())
result = a(n)
print(result)
```
